The system consists of:

1) A **rotating clamp** that can be attached to the operating table side rails over the drapes.

2) A **vertical bar** that fits into the clamp and comes above the side of the table.

3) A **horizontal attachment** that fits over the vertical bar and can swing over the wound.

4) A threaded **tightening rod** that inserts through a slot in the arm of the horizontal attachment and can be used to bring up the proximal femur.

5) A large **offset femoral hook** that can be placed above the lesser trochanter and around the posterior femoral neck and trochanter base. The handle of the hook has a chain to attach to the threaded tightening rod coming through the horizontal arm.

Used for femoral preparation after the acetabular component has been implanted.
